

Enumeration

Increasing attack vectors. Decreasing the path gives the right direction.

- The attacker creates an **active** connection to the system and performs **directed queries** to gain **more info** about the target.
- Attackers establish an active connection with the victim and discover as many **attack vectors** as possible.
- Enumeration techniques are conducted in an **intranet** environment.
- Scanning is finding an attack surface, enumeration is **expanding** it.
- Enumeration is the **key** to a successful penetration test.

Information enumerated by Intruders:

- Network resources
- Network shares
- Routing tables

Enumeration Techniques:

- Extract user names using email IDs
- Extract information using the default passwords

- Audit and service settings
- SNMP and DNS details
- Machine names
- Users and Groups
- Application and banners

- passwords**
- Extract user names using SNMP
 - Brute force Active Directory
 - Extract user groups from Windows
 - Extract information using DNS Zone Transfer

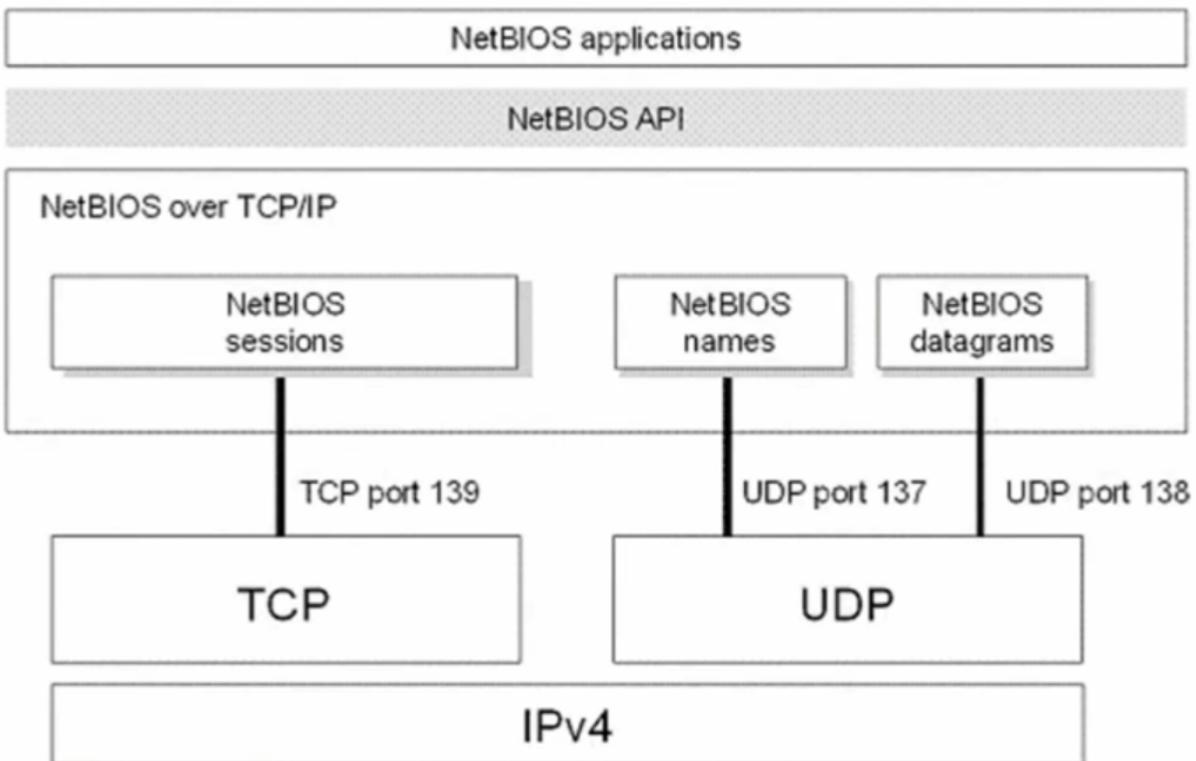

▼ Services and Ports to Enumerate

- TCP/UDP **53**: DNS Zone Transfer
- TCP/UDP **135**: Microsoft RPC Endpoint Mapper
- UDP **137**: NetBIOS Name Service (**NBNS**)
- TCP **139**: NetBIOS Session Service (**SMB over NetBIOS**)
- TCP/UDP **445**: SMB over TCP (**Direct Host**)
- UDP **161**: Simple Network Management Protocol (**SNMP**)
- TCP/UDP **389**: Lightweight Directory Access Protocol (**LDAP**)
- TCP/UDP **3268**: Global Catalog Service
- TCP **25**: Simple Mail Transfer Protocol (**SMTP**)
- TCP/UDP **162**: SNMP Trap

1. **NetBIOS Enumeration**

- NetBIOS (Network Basic Input/Output System) is a program that allows **applications** on **different** computers to **communicate** within a local area network(**LAN**).
- Created by IBM, adopted by Microsoft

- NetBIOS is basically an API via Microsoft to share Windows information.
- Information from Windows is passed to NetBIOS API and that data is transferred to TCP/IP packets, further circulating on the network.
- NetBIOS name is a unique 16 ASCII character string used to identify the network devices over TCP/IP, 15 characters are used for the device name, and the 16th character is reserved for the service or name record type.
 - Software applications on a NetBIOS network locate and identify each other via their NetBIOS name.
 - Applications on other computer access NetBIOS names over UDP(NBNS).
 - NetBIOS used 3 ports (137, 138, 139) 138 sending datagram packets for connectionless service UDP.
 - Two applications start a NetBIOS session when the client sends a command to “call” another client (the server) over TCP port 139. (session mode).
 - The “hand-up” command terminates a NetBIOS session.
 - NOTE: NetBIOS name resolution is not supported by Microsoft for Internet Protocol version 6 (IPV6).

An attacker uses the NetBIOS enumeration to obtain:

- List of **computers** that belong to **Domain**.
- List of **shares** on the **individual** hosts in the network.
- **Policies** and **passwords**

Using NetBIOS enumeration he can perform:

- **Read/Write** to a **shared resource** depending on the availability of shares
- Launch **DOS** on the target
- **Enumerate password policies**

Tools:

- Nbstat

It is Utility tool in Windows to display NetBIOS over TCP/IP(NetBT) protocol statistics, NetBIOS name table for both the local and remote computers, and NetBIOS name cache.

```
nbstat.exe -c
```

- Get the contents of the NetBIOS name cache, the table of NetBIOS names, and their resolved IP address.

```
nbstat.exe -a IPaddress_of_remote_machine
```

- Gets the NetBIOS name table of a remote computer.

2. SMB Enumeration

- SMB stands for **Server Message Block** used for **sharing resources** like files, printers, and any resources that should be **retrievable** or made available by the **server**.
- It runs on port **445** or port **139** (NetBIOS) depending on the server, natively available in **Windows**.
- To make it work for **Linux**, you need to install a **samba** server because Linux natively does not use SMB protocol.
- Operates on **Layer 7**, and uses **TCP/IP** on 445 for transport.

▼ SMB Implementation

CIFS, Samba, NQ, MoSMB, Tuxera SMB

SMB used either IP port 139 or 445

- Port 139: SMB originally ran on top of NetBIOS using port 139. NetBIOS is an **older transport layer** that allows Windows computers to talk to each other on the **same network**.
- Port 445: Later version of SMB (After Windows 2000) began to use **445** on top of the **TCP stack**. Using TCP allows SMB to work over the **internet**.

Tools:

- smbclient
- smbman
- Nmap

SMBCLIENT

```
smbclient -L 192.168.229.129

```

3. SNMP Enumeration

- Simple Network Management Protocol is an **application layer** protocol that uses **UCP** to **maintain** and **manage** routers, hubs and switches, and other **network devices** on an IP network.
- SNMP enumeration is used to enumerate and gather information on user accounts, passwords, groups, system names, and devices on a target system.
- SNMP consists of a manager and an agent. Two parties
 - Agents are embedded in every network device

- A manager is installed on a separate computer

Components of SNMP:

- Managed Device: A managed device is a device or **host** which has the SNMP **service enabled**. These devices could be routers, switches, hubs, bridges, computers, etc.
- Agent: An agent can be thought of as a piece of **software** that runs on the **managed** device. Its primary job is to **convert** the **information** into **SNMP-compatible** format for smoother management of the network using SNMP protocol.
- Network Management System: These are the software used to **monitor** network devices.

▼ SNMP holds two passwords to access and configure the SNMP agent from the management station:

- Read community string: It is **public** by default and allows viewing of device/sys configuration.
- Read/Write community string: It is **private** by default and allows remote editing of configuration.

The attacker uses these **default** strings or brute-forcing to extract information about a device and information about

network resources such as hosts, routers, devices, shares, etc., and ARP tables, routing tables, traffic, etc.

Management Information Base (MIB)

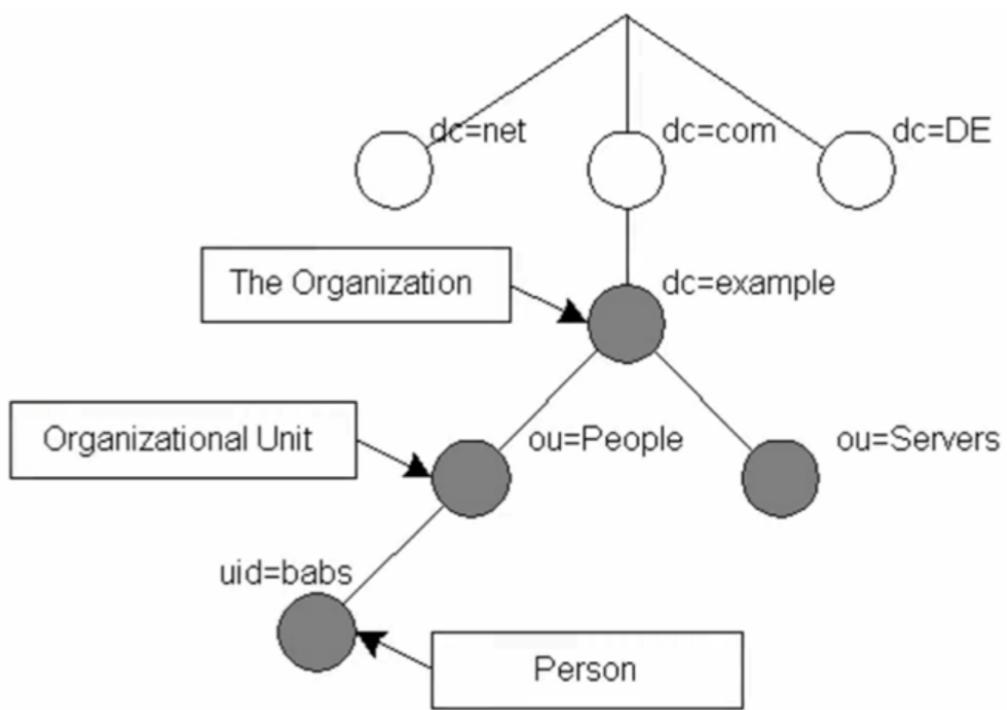

- MIB is a **virtual database** containing a formal **description** of all the network **objects** that can be managed using SNMP.
 - The MIB database is **hierarchical** and each managed **object** in a MIB is **addressed** through **Object Identifier**(OIDs).
 - Two types of managed objects exist:
 - Scalar objects that define a single object instance.
 - Tabular objects that define multiple related object instances are grouped in MIB tables.
-

4. LDAP Enumeration

- A **lightweight Directory Access Protocol** is an **internet protocol** for **accessing distributed directory services**.
- Is a **Hierarchical compilation** used to **access** directory listings within **Active Directory** or from other **Directory Services**.
- An LDAP session is established by the **client** by connecting **Directory System Agent (DSA)** on **TCP port 389** and sending an **operation request** to the DSA. Then receives encoded information (not Encrypted)from DSA and LDAPS all data are transmitted in plain text form.
- Information is transmitted between the client and server using **Basic Encoding Rules (BER)**.
- Attacker queries LDAP service to gather information such as valid **user names, addresses, departmental details**, etc. that can be further used to perform attacks.

Attribute	Field	Usage
CN	Common Name	Identifies the person or object.
OU	Organizational Unit	A unit or department within the organization.
O	Organization	The name of the organization.
L	Locality	Usually a city or area.
ST	State	A state, province, or county within a country.
C	Country	The country's 2-character ISO code (such as c=US or c=GB).
DC	Domain Component	Components of the object's domain.

Hierarchical Structure

5. SMTP Enumeration

- A simple Mail Transfer Protocol is used to send emails to local or remote mail servers.
 - To receive mail either POP or IMAP are used.
- SMTP provides 3 built-in commands:

- VRFY: **Valid** users
- EXPN: Tells the actual **delivery addresses** of aliases and mailing lists
- RCPT: Defines the **recipients** of the message
- SMTP servers **respond differently** to VRFY, EXPN, RCPT if **invalid** users when enumeration.
- Attackers can directly interact with SMTP via **telnet** prompt and **collect a list** of valid users on the SMTP server.

Tools:

- smtp
- Metasploit

6. DNS Enumeration (Zone transfer)

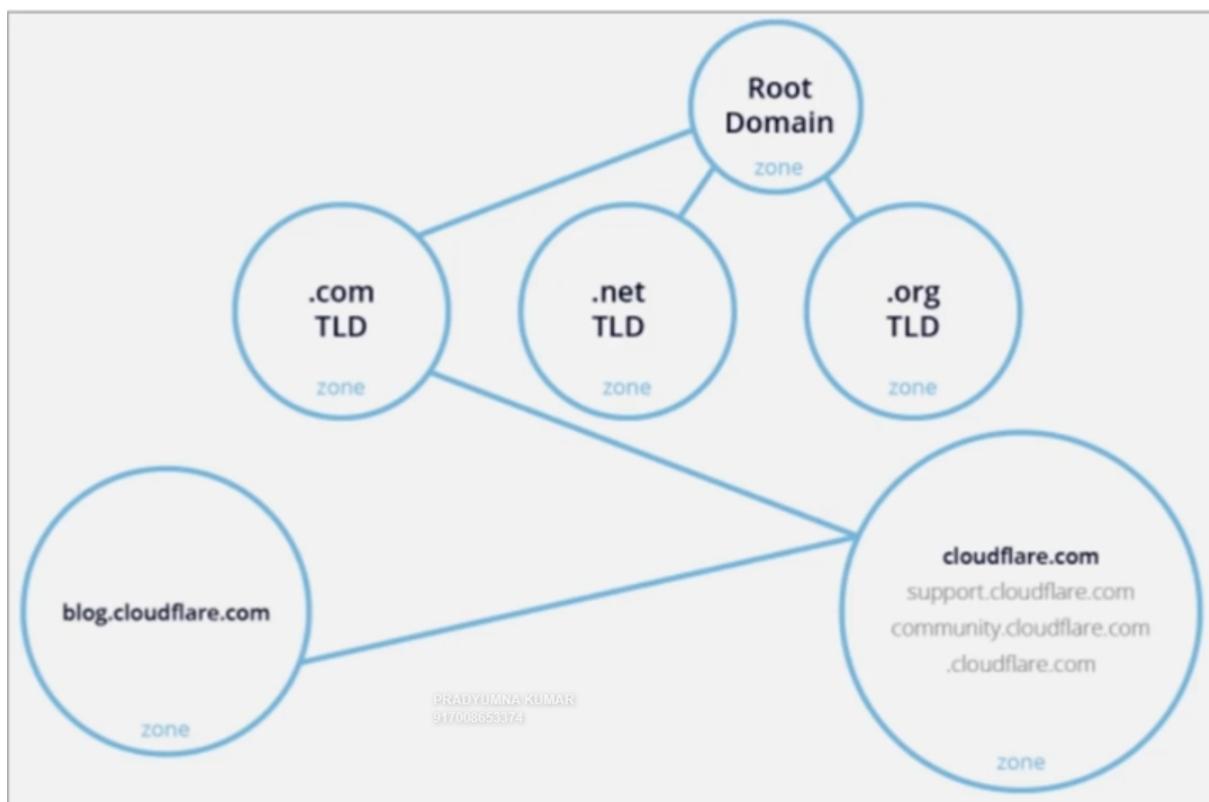

- It is a process of locating the DNS server and records of the target network.
- An attacker can gather information such as the DNS server name, hostname, machine names, username, and IP address of potential targets.
- The DNS implements a distributed, hierarchical, and redundant database for information associated with Internet domain names and addresses.
- In DNS zone transfer enumeration, the attacker tries to retrieve a copy of the entire zone file for a domain from the DNS server.

DNS Zone

- It is a **portion of the DNS namespace** that is **managed** by a specific organization or **administrator**.
- It is an **administrative space** that allows for more **managed/granular** control of DNS components, such as an

authoritative name server.

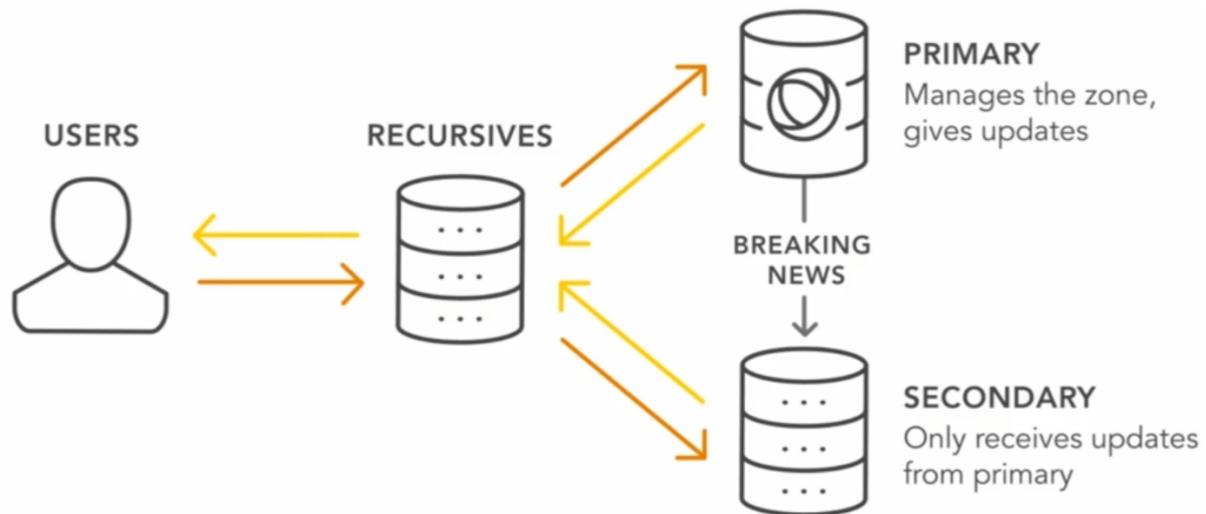

- Granular control changes in the smallest level by separating them with different types of records for faster search.
- In fact, a DNS can contain multiple subdomains and multiple zones can exist on the same server.
- DNS zones are not necessarily physically separated from one another, zones are strictly used for delegating control.

- All the **information for a zone** is stored in **DNS zone file**, the key to understanding zone operation.
- A zone file is a **plain text** file stored in DNS server that contains an actual **representation** of zone and contains **all** the **records** for every domain within zone.
- Zone file must always **start** with a **Start of Authority** record, which contains important information including **contact information** for the zone **administrator**.

Zone Transfer

- A **primary** DNS server only has the master copy of the zone, and a **secondary** DNS will have a copy of zone for **redundancy**.
- Whenever there is a **change** in the zone data on the primary DNS, then the changes have to be **shared** to the secondary DNS of the zone. This is Zone Transfer.
- A zone transfer uses the **TCP** for transport and takes the form of a client-server **transaction**.

- Zone transfers are **automatically** triggered when the zone **serial number** increments (the number increases). The zone serial number increments when the zone receives an **update**.
- A zone transfer can be full or incremental.
 - Full zone transfers are referred to as **AXFR** (Asynchronous full transfer or authoritative full transfer)
 - Incremental zone transfers are **IXFR** (Incremental transfer)
- AXFR offers no authentication, so any client can ask a DNS server for a copy of the entire zone.
- This means that unless some kind of protection is introduced, an attacker can get a list of all hosts for a domain, which gives them a lot of potential attack vectors.

Tools:

- host
- nslookup
- dig

host:

```
host -t ns zonetransfer.me
host -l zonetransfer.me name_server
```

nslookup:

- By default give A records

```
nslookup
> set type=a
> google.com

> set type cname
> google.com
```

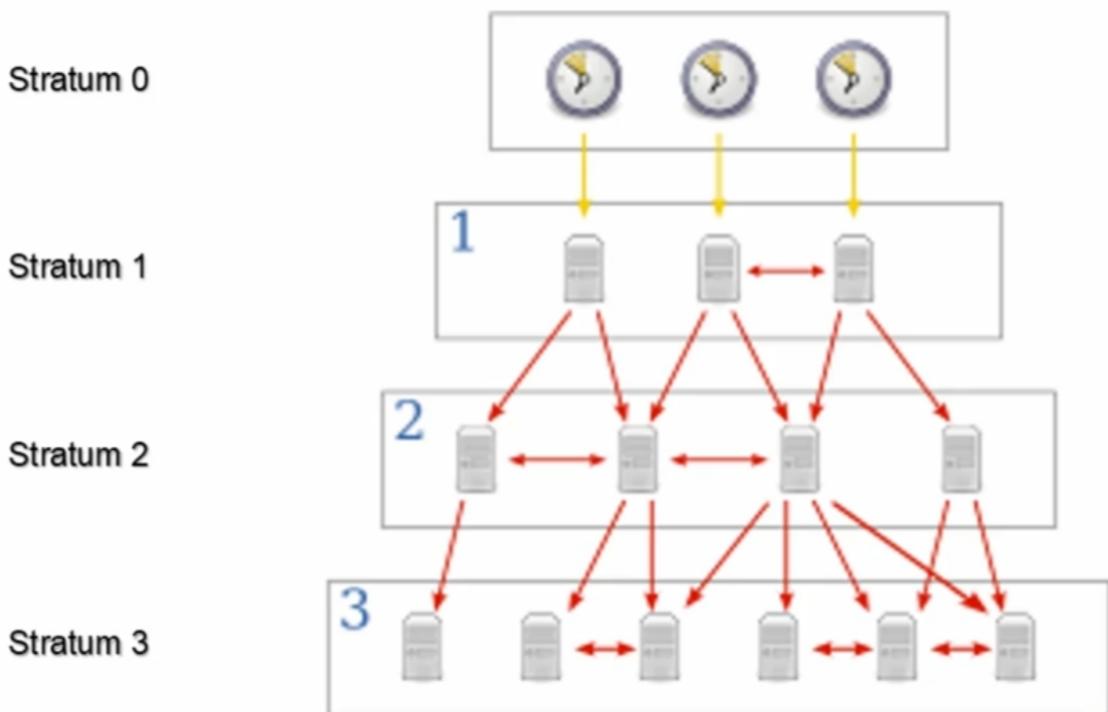

```
nslookup
> set type=ns      [ Name Server ]
> TLD
> server nsztml.digi.ninja
> set type=any
ls -d maindomain.TLD
```

dig full zone transfer:

```
dig axfr @name.serv.er domain.TLD
```

NTP Enumeration

- Network Time Protocol is designed to synchronize clocks of networked computers.
- It uses UDP port 123 as its primary means of communication.
- NTP can maintain time to within 10 millisecond (1/100 sec) over the public internet.
- It can achieve accuracies of 200 microsec or better in local area networks under ideal conditions.
- Attacker queries NTP server to gather valuable information such as:
 - List of hosts connected to NTP server
 - Clients IP addresses in a network, their system names and OSs
 - Internal IPs can also be obtained NTP server is in the DMZ

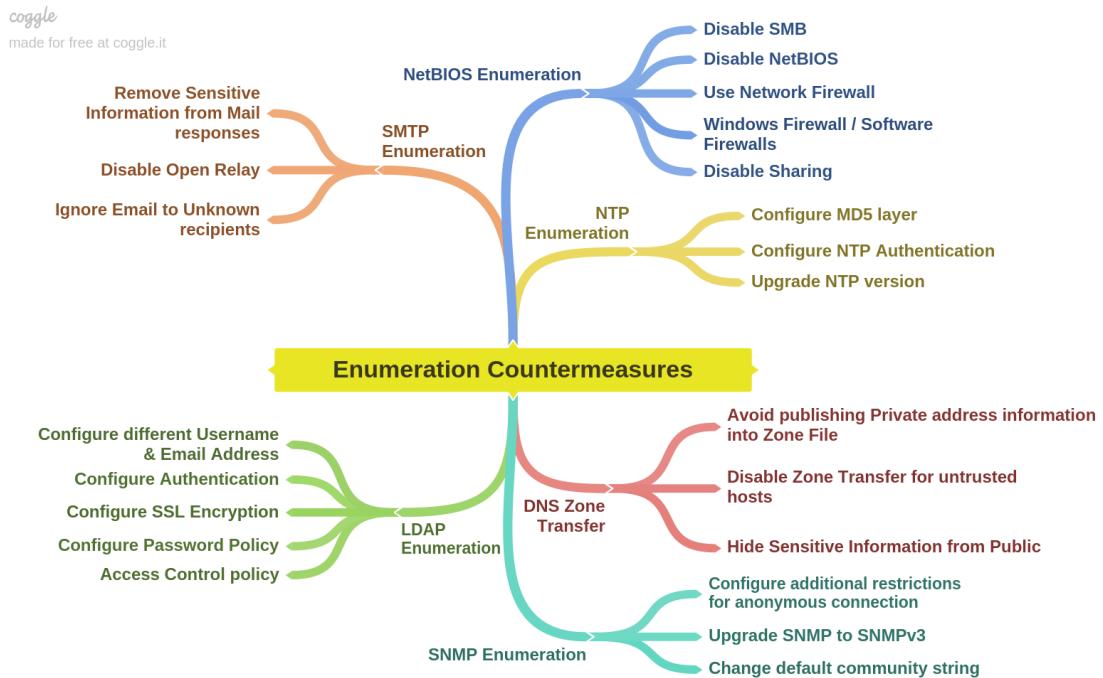

Enumeration Countermeasures

- NetBIOS:

- Disable SMB (Under Windows Features)
 - Disable NetBIOS (Under Network TCP/IP setting)
 - Use Network Firewall
 - Use Windows/Software Firewalls
 - Disable Sharing
- SNMP:
 - Remove SNMP agent(MIB is present in agent) or turn off the SNMP service
 - If shutting off SNMP is not an option, then change the default community string name
 - Upgrade to SNMP3, which encrypts passwords and messages
 - Implement the Group Policy security option called "Additional restrictions for anonymous connections"
 - Ensure that access to null session pipes, null session shares, and IPSec filtering is restricted. (Proper session should be established)
- DNS:
 - Disable DNS zone transfer to untrusted hosts
 - Make sure private hosts and IP addresses are not published into DNS zone files of public DNS server
 - Use premium DNS registration services (GoDaddy) that hide sensitive information such as HINFO from public
 - Use standard network admin contact for DNS registration in order to avoid social engineering attacks
- SMTP:
 - Configure SMTP servers to
 - Ignore email messages to unknown recipients
 - Not include sensitive mail server like location, IP, and local host information

- Disable the open relay feature
- LDAP:
 - By default, LDAP traffic is transmitted unsecured; Use SSL technology to encrypt the traffic
 - Select a user name different from your email address and enable account lockout if a failed login attempt is made
 - Configure password policy
 - Configure access control policy
- SMB:
 - Disable SMB protocol on Web and DNS servers
 - Disable SMB protocol on internet-facing servers
 - Disable ports TCP 139 and TCP 445 used by SMB protocol
 - Restrict anonymous access through RestrictNullSessAccess parameter from the Windows Registry
- NTP:
 - Configure MD5 layer (Hashing)
 - Configure NTP Authentication
 - Upgrade NTP version
